# MTH 9875 The Volatility Surface: Fall 2015

## Lecture 9: The SVI volatility surface parameterization

Jim Gatheral Department of Mathematics

The City University of New York

## **Outline of lecture 9**

- No-arbitrage constraints on the tail behavior of implied volatility.
- The SVI parameterization of the volatility smile and its variants.
  - Sufficient conditions for no calendar-spread arbitrage.
  - Necessary and sufficient conditions for no calendar-spread arbitrage.
  - Arbitrage on a slice.
- Generating an implied volatility surface from raw index option data.
- Visualization:
  - Total variance plot.
  - 3D plot.
- Fitting SVI subject to no-arbitrage constraints.

## Roger Lee's Moment Formula

- [Roger Lee]<sup>[6]</sup> shows that implied variance is bounded above by a function linear in the log-strike  $k = \log(K/F)$  as  $|k| \to \infty$ .
  - The maximum slope of total implied variance  $w(k,T)=\sigma_{BS}^2(k,T)\,T$  is 2.
- He shows how to relate the gradients of the wings of the upper bound of the implied variance skew to the maximal finite moments of the underlying process.
- Lee's derivation assumes only the existence of a martingale measure: it makes no assumptions on the distribution of underlying returns. His result is completely modelindependent.

## The Roger Lee Moment Formula

#### Roger Lee's Lemma 3.1

There exists  $k^{\star}>0$  such that for all  $k>k^{\star}$  ,

$$\sigma_{BS}^2(k) < 2\,rac{|k|}{T}.$$

#### Proof.

We only need to show that  $C_{BS}\left(k,\sigma_{BS}(k)\,\sqrt{T}
ight) < C_{BS}\left(k,\sqrt{2\,|k|}
ight)$  whenever  $k>k^{\star}$  .

On the LHS, we have

$$\lim_{k o\infty}C_{BS}\left(k,\sigma_{BS}(k)\,\sqrt{T}
ight)=0$$

and on the RHS, we have

$$egin{aligned} &\lim_{k o\infty} C_{BS}\left(k,\sqrt{2\left|k
ight|}
ight) \ = \ \lim_{k o\infty} F\left\{N(d_1) - e^k\,N(d_2)
ight\} \ &= \lim_{k o\infty} F\left\{N(0) - e^k\,N(-\sqrt{2\left|k
ight|})
ight\} = rac{F}{2} \end{aligned}$$

# The left wing

Specifically, let 
$$q^*:=\supig\{q:\mathbb E\,S_T^{-q}<\inftyig\}$$
 and 
$$\beta^*:=\limsup_{k o-\infty}rac{\sigma_{BS}^2(k,T)\,T}{|k|}$$

Then  $eta^* \in [0,2]$ ,

$$q^* = rac{1}{2}igg(rac{1}{\sqrt{eta^*}} - rac{\sqrt{eta^*}}{2}igg)^2$$

and inverting this, we obtain  $eta^*=g(q^*)$  with  $g(x)=2-4\,\left\lceil\sqrt{x^2+x}-x
ight
ceil$ 

# The right wing

Similarly, let 
$$p^*:=\sup\left\{p:\mathbb{E}\,S_T^{1+p}<\infty
ight\}$$
 and  $lpha^*:=\limsup_{k o +\infty}rac{\sigma_{BS}^2(k,T)\,T}{|k|}$ 

Then  $lpha^* \in [0,2]$ ,

$$p^* = rac{1}{2}igg(rac{1}{\sqrt{lpha^*}} - rac{\sqrt{lpha^*}}{2}igg)^2$$

and as for the left wing, it follows that  $lpha^*=g(p^*)$  .

#### **Benaim and Friz**

- With F(x) the CDF, [Benaim and Friz]<sup>[1]</sup> go on to show that Roger Lee's upper bound (  $\limsup$  ) may be replaced by a limit in most practical cases.
- · Then we may write for the right tail

$$rac{\sigma_{BS}(k,T)^2\,T}{k}\sim g\left(-1-rac{\log\left[1-F(k)
ight]}{k}
ight) ext{ as } k o\infty$$

and for the left tail

(2) 
$$rac{\sigma_{BS}(-k,T)^2\,T}{k}\sim g\left(rac{-\log F(-k)}{k}
ight) ext{ as } k o\infty$$

• By substituting the tail-behavior of F into equations [(1)](#eq1:benaimr) and [(2)] (#eq2:benaiml), we can deduce the full tail behavior of the smile, not just Roger Lee's upper bound.

# **Example: Black-Scholes**

$$egin{align} 1 - F(k) = & \int_k^\infty rac{1}{\sqrt{2\,\pi\,\sigma^2\,T}}\,e^{-y^2/(2\sigma^2\,T)}\,dy \ & \sim & rac{1}{\sqrt{2\,\pi}}\,rac{e^{-k^2/(2\,\sigma^2\,T)}}{k}\,\mathrm{as}\;k o \infty \end{array}$$

Then

$$\log\left[1-F(k)
ight] \sim -rac{k^2}{2\,\sigma^2\,T} ext{ as } k o \infty$$

and

$$rac{\sigma_{BS}(k,T)^2\,T}{k}\sim g\left(-1+rac{k}{2\,\sigma^2\,T}
ight)\simrac{2\,\sigma^2\,T}{2\,k} ext{ as } k o\infty$$

It follows that

$$\sigma_{BS}(k,T)^2 \sim \sigma^2 ext{ as } k o \infty$$

### Implications of the moment formula

- Implied variance is linear in k as  $k \to \infty$  for stochastic volatility models.
- So, if we want a parametrization of the implied variance surface consistent with stochastic volatility, it needs to be linear in the wings!
  - and it needs to be curved in the middle many conventional parameterizations of the volatility surface are quadratic for example.

# **History of SVI**

- SVI was originally devised at Merrill Lynch in 1999 and subsequently written up in detail in [Gatheral and Jacquier]<sup>[5]</sup>.
- SVI has two key properties that have led to its subsequent popularity with practitioners:
  - For a fixed time to expiry t, the implied Black-Scholes variance  $\sigma_{\mathrm{BS}}^2(k,t)$  is linear in the log-strike k as  $|k| \to \infty$  consistent with Roger Lee's moment formula [Roger Lee] [6].
  - It is relatively easy to fit listed option prices whilst ensuring no calendar spread arbitrage.
- As shown in [Gatheral and Jacquier]<sup>[4]</sup>, the SVI parameterization is not arbitrary in the sense that the large-maturity limit of the Heston implied volatility smile is exactly SVI.

## Characterisation of static arbitrage

#### **Definition 2.1**

A volatility surface is free of static arbitrage if and only if the following conditions are satisfied: (i) it is free of calendar spread arbitrage; (ii) each time slice is free of butterfly arbitrage.

## Calendar spread arbitrage

#### Lemma 2.2

If dividends are proportional to the stock price, the volatility surface w is free of calendar spread arbitrage if and only if  $\partial_t w(k,t) \geq 0$ , for all  $k \in \mathbb{R}$  and t > 0.

 Thus there is no calendar spread arbitrage if there are no crossed lines on a total variance plot.

#### Proof of Lemma 2.2

- ullet For any martingale  $X_t$  and  $t_2 \geq t_1$ ,  $\mathbb{E}\left[(X_{t_2}-L)^+
  ight] \geq \mathbb{E}\left[(X_{t_1}-L)^+
  ight]$
- Define  $F_{0,t} := \mathbb{E}[S_t | \mathcal{F}_0]$ .
- Let  $C_i$  be options with strikes  $K_i$  and expirations  $t_i$  with  $t_2>t_1$ . Suppose the two options have the same moneyness so that

$$\frac{K_1}{F_{0,t_1}} = \frac{K_2}{F_{0,t_2}} =: e^k$$

- Then, if dividends are proportional,  $X_t := S_t/F_{0,t}$  is a martingale and

$$rac{C_2}{K_2} = e^{-k} \mathbb{E}\left[\left(X_{t_2} - e^k
ight)^+
ight] \geq e^{-k} \mathbb{E}\left[\left(X_{t_1} - e^k
ight)^+
ight] = rac{C_1}{K_1}.$$

- So, if dividends are proportional, keeping moneyness constant, option prices are nondecreasing in time to expiration.
- Let  $w_t := \sigma^2_{BS}(k,T)\,T$  .
- The Black-Scholes formula for the non-discounted value of an option may be expressed in the form  $C_{BS}(k,w_t)$  with  $C_{BS}(\cdot)$  strictly increasing in the total implied variance  $w_t$ .
- It follows that for fixed k, we must have the total implied variance  $w_t$  non-decreasing with respect to time to expiration:

# No calendar spread arbitrage condition

$$\partial_t w(k;\chi_t)\geqslant 0$$

where  $\chi_t$  denotes the t-dependent parameters of our fit.

# **Butterfly arbitrage**

#### **Definition 2.3**

A slice is said to be free of butterfly arbitrage if the corresponding density is non-negative.

Now introduce the function  $g:\mathbb{R} o \mathbb{R}$  defined by

$$g(k) := \left(1 - rac{kw'(k)}{2w(k)}
ight)^2 - rac{w'(k)^2}{4} \left(rac{1}{w(k)} + rac{1}{4}
ight) + rac{w''(k)}{2}.$$

#### Lemma 2.4

A slice is free of butterfly arbitrage if and only if  $g(k)\geq 0$  for all  $k\in\mathbb{R}$  and  $\lim_{k\to+\infty}d_+(k)=-\infty.$ 

### The raw SVI parameterization

For a given parameter set  $\chi_R = \{a, b, \rho, m, \sigma\}$ , the \*raw SVI parameterization\* of total implied variance reads:

#### **Raw SVI parameterization**

$$w(k;\chi_R) = a + b \, \left\{ 
ho \left( k - m 
ight) + \sqrt{\left( k - m 
ight)^2 + \sigma^2} 
ight\}$$

where  $a\in\mathbb{R}$ ,  $b\geq 0$ ,  $|\rho|<1$ ,  $m\in\mathbb{R}$ ,  $\sigma>0$ , and the obvious condition  $a+b\,\sigma\,\sqrt{1-\rho^2}\geq 0$ , which ensures that  $w(k,\chi_R)\geq 0$  for all  $k\in\mathbb{R}$ . This condition ensures that the minimum of the function  $w(\cdot,\chi_R)$  is non-negative.

# An SVI example

Here's a specific choice of parameters:

And here's how the SVI smile looks with these parameters:

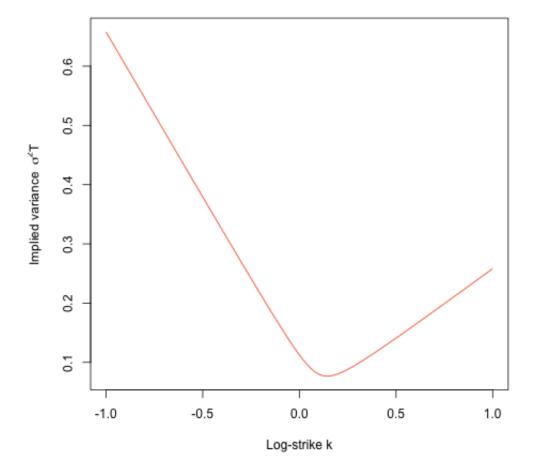

Figure 1: The SVI smile with  $a=0.04,\,b=0.4,\,\sigma=0.1,\,\rho=-0.4,\,m=0$ 

### Meaning of raw SVI parameters

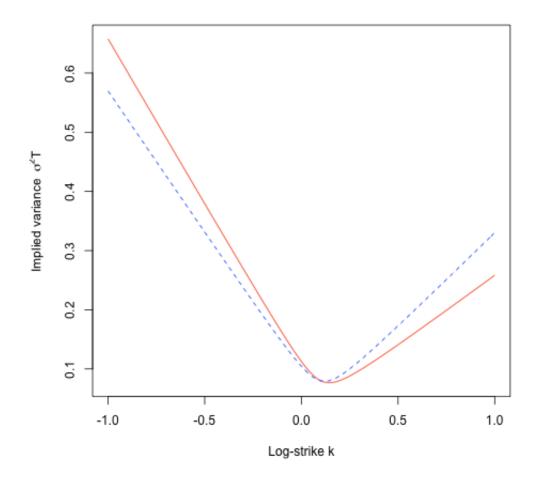

Changes in the parameters have the following effects:

- Increasing a increases the general level of variance, a vertical translation of the smile;
- Increasing b increases the slopes of both the put and call wings, tightening the smile;
- Increasing  $\rho$  decreases (increases) the slope of the left(right) wing, a counter-clockwise rotation of the smile;
- Increasing *m* translates the smile to the right;
- Increasing  $\sigma$  reduces the at-the-money (ATM) curvature of the smile.

We can convince ourselves that if the wings are linear in k, we need 5 and only 5 parameters to cover all reasonable transformations of the volatility smile.

## Demonstrate the effect of changing raw SVI parameters:

```
In [10]: sviparams <- list(a = 0.04, b = 0.4, sig = 0.1, rho = - 0.4, m = 0.1)
    curve(svi(sviparams,x),from=-1,to=1,col="red",xlab="Log-strike k",ylab=e
    xpression(paste("Implied variance ",sigma^2*T)))
    sviparams2 <- sviparams
    sviparams2$rho <- sviparams$rho + 0.2
    curve(svi(sviparams2,x),from=-1,to=1,col="blue",add=T, lty=2)</pre>
```

### The natural SVI parameterization

For a given parameter set  $\chi_N=\{\Delta,\mu,\rho,\omega,\zeta\}$ , the \*natural SVI parameterization\* of total implied variance reads:

**Natural SVI parameterization** 

$$w(k;\chi_N) = \Delta + rac{\omega}{2} \Bigl\{ 1 + \zeta 
ho \left( k - \mu 
ight) + \ \sqrt{ \left( \zeta (k - \mu) + 
ho 
ight)^2 + \left( 1 - 
ho^2 
ight)} \Bigr\}$$

where  $\omega \geq 0$ ,  $\Delta \in \mathbb{R}$ ,  $\mu \in \mathbb{R}$ ,  $|\rho| < 1$  and  $\zeta > 0$ .

• This parameterization is a natural generalization of the time  $\infty$  Heston smile explored in [Gatheral and Jacquier]<sup>[4]</sup>.

### The SVI Jump-Wings (SVI-JW) parameterization

- Neither the raw SVI nor the natural SVI parameterizations are intuitive to traders.
- There is no reason to expect these parameters to be particularly stable.
- The \*SVI-Jump-Wings (SVI-JW) parameterization\* of the implied variance v (rather than the implied total variance w) was inspired by a similar parameterization attributed to Tim Klassen, then at Goldman Sachs.

#### **SVI-JW**

For a given time to expiry t>0, and an SVI total variance smile w(k), the SVI-JW parameters are defined as follows:

#### **SVI-JW** parameterization

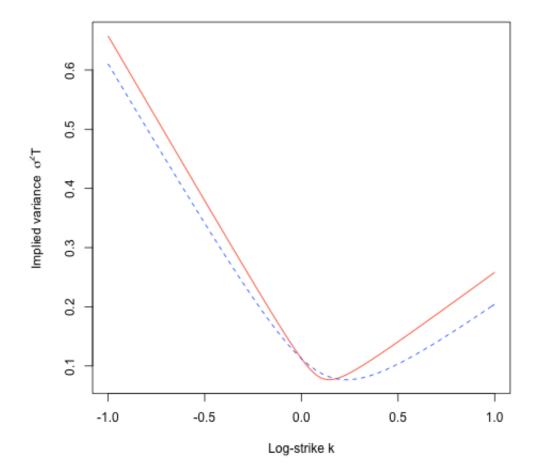

$$egin{aligned} v_t &= w(0)/t, \ \psi_t &= rac{\partial \sqrt{w(k)}}{\partial k}igg|_{k=0} = \sqrt{t} \, rac{\partial \sigma_{BS}(k,t)}{\partial k}igg|_{k=0}, \ p_t &= \lim_{k o -\infty} -rac{1}{\sqrt{\overline{w(0)}}} \, rac{\partial w(k)}{\partial k}, \ c_t &= \lim_{k o +\infty} rac{1}{\sqrt{\overline{w(0)}}} \, rac{\partial w(k)}{\partial k}, \ ilde{v}_t &= \min_{k\in \mathbb{R}} w(k)/t. \end{aligned}$$

## Interpretation of SVI-JW parameters

The SVI-JW parameters have the following interpretations:

- $v_t$  gives the ATM variance;</span>
- $\psi_t$  gives the ATM skew;</span>
- $p_t$  gives the slope of the left (put) wing;
- $c_t$  gives the slope of the right (call) wing;
- $ilde{v}_t$  is the minimum implied variance.

# Demonstrate the effect of changing SVI-JW parameters:

## Scaling of SVI Jump-Wings parameters with volatility

Note that, as defined here,

$$\psi_t = \left. rac{\partial \sigma_{BS}(k)}{\partial k} 
ight|_{k=0}$$

The choice of volatility skew as the skew measure rather than variance skew for example, reflects the empirical observation that volatility is roughly lognormally distributed. Specifically, we show in Chapter 7 of *The Volatility Surface* that if the SDE for variance is of the form:

$$dv = -\lambda (v - \overline{v}) dt + \eta \sqrt{v} \beta(v) dZ$$

we should have

$$rac{\partial}{\partial k}\,\sigma_{BS}(k,T)^2\,pprox\,rac{
ho\,\eta\,eta(v)}{\lambda'\,T} \Biggl\{1-rac{\left(1-e^{-\lambda'T}
ight)}{\lambda'\,T}\Biggr\} \propto eta(v)$$

with  $\lambda' = \lambda - rac{1}{2} \, 
ho \, \eta \, eta(v)$  .

Thus

$$\left.rac{\partial\sigma_{BS}(k)}{\partial k}
ight|_{k=0}pprox ext{const.}$$

independent of volatility implies that

$$eta(v) \sim \sqrt{v}$$

and therefore that the variance (volatility) process is lognormal.

This consistency of the SVI-JW parameterization with empirical volatility dynamics leads to greater parameter stability over time.

## Scaling of SVI Jump-Wings parameters with time to expiration

- If smiles scaled perfectly as  $1/\sqrt{w_t}$  (effectively  $1/\sqrt{t}$  in practice), SVI-JW parameters would be constant, independent of the slice t.
  - This makes it easy to extrapolate the SVI surface to expirations beyond the longest expiration in the data set.
- Since both scaling features are roughly consistent with empirical observation, we expect (and see) greater parameter stability over time.
  - Traders can keep parameters in their heads.

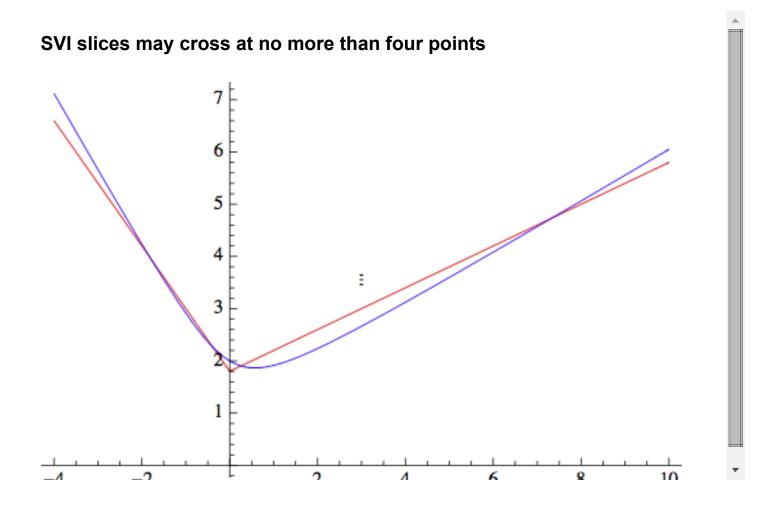

Figure 2: Lines cross at four points here.

# Condition for no calendar spread arbitrage

#### Lemma 3.1

Two raw SVI slices admit no calendar spread arbitrage if a certain quartic polynomial has no real root.

#### Ferrari Cardano

The idea is as follows:

· Two total variance slices cross if

$$a_{1}+b_{1}\left\{ 
ho_{1}\left(k-m_{1}
ight)+\sqrt{\left(k-m_{1}
ight)^{2}+\sigma_{1}^{2}}
ight\} \ =a_{2}+b_{2}\left\{ 
ho_{2}\left(k-m_{2}
ight)+\sqrt{\left(k-m_{2}
ight)^{2}+\sigma_{2}^{2}}
ight\}$$

</span>

· Rearranging and squaring gives a quartic polynomial equation of the form

$$\alpha_4 k^4 + \alpha_3 k^3 + \alpha_2 k^2 + \alpha_1 k + \alpha_0 = 0,$$

where each of the coefficients are lengthy yet explicit expressions in terms of the raw SVI parameters. </span>

- If this quartic polynomial has no real root, then the slices do not intersect.
- Roots of a quartic polynomial are known in closed-form thanks to [Cardano]<sup>[2]</sup>.

## SVI butterfly arbitrage

Recall the definition:

$$g(k) := \left(1 - rac{kw'(k)}{2w(k)}
ight)^2 - rac{w'(k)^2}{4} igg(rac{1}{w(k)} + rac{1}{4}igg) + rac{w''(k)}{2}.$$

- The highly nonlinear behavior of *g* makes it seemingly impossible to find general conditions on the parameters that would eliminate butterfly arbitrage.
- We now provide an example where the no-butterfly-arbitrage condition is violated.

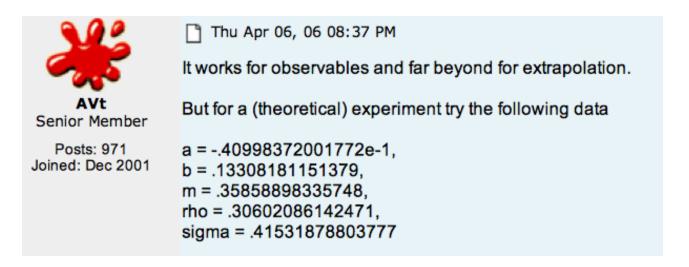

```
In [13]: # Butterfly g(.) function
g <- function(sviparams,k){

    a <- sviparams$a;
    b <- sviparams$b;
    sig <- sviparams$sig;
    rho <- sviparams$rho;
    m <- sviparams$m;

    discr <- sqrt((k-m)*(k-m) + sig*sig);
    w <- a + b *(rho*(k-m)+ discr);
    dw <- b*rho + b *(k-m)/discr;
    d2w <- b*sig^2/(discr*discr*discr);

    return(1 - k*dw/w + dw*dw/4*(-1/w+k*k/(w*w)-4) +d2w/2);
}</pre>
```

## **Axel Vogt post on Wilmott.com**

# The Vogt smile

Now let's take a look at the smile and graph the function g(k):

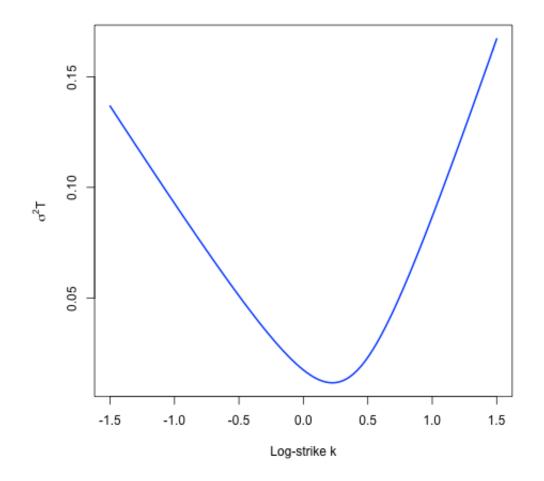

Figure 3: Plot of the total variance smile w using Axel Vogt's parameters.

```
In [16]: # Then the graph of g(.)
    curve(g(vogtParams,x),from=-r,to=r,col="blue",n=500,lwd=2,ylab=expressio
    n(g(k)),xlab="Log-strike k")
    lines(c(-r,r),c(0,0),lty=2)
```

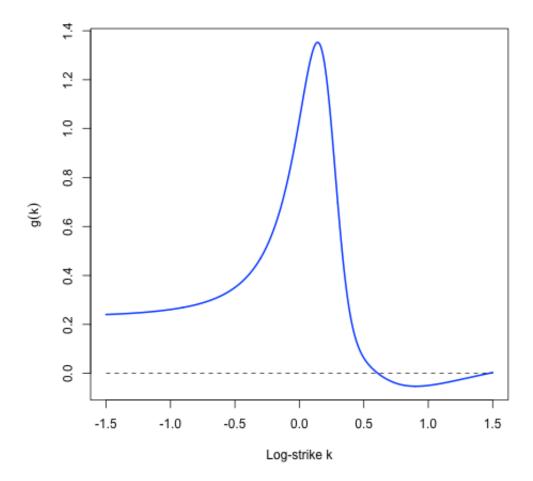

Figure 4: Plots of the function g, using Axel Vogt's parameters

• We see that the function  $g(\cdot)$  and so the density goes negative with the Vogt parameters.

We knew already that there could be arbitrage on a slice with SVI and Axel Vogt has given us an embarrassing example. In fact, we can generate arbitrage even with  $\rho=0$ . Let's redo the plots:

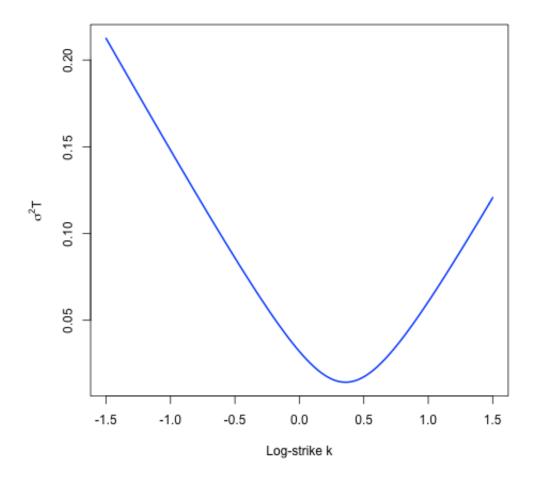

Figure 5: Plots of the total variance smile w(k,T) using Axel Vogt's parameters, except with ho=0 .

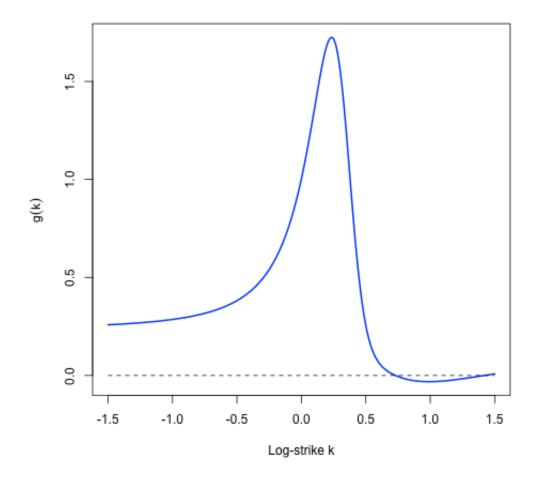

Figure 6: Plots of the function g(k) (bottom), using Axel Vogt's parameters, but with ho=0 .

Until 2012 or so, I thought there was no simple way to guarantee the absence of butterfly arbitrage.

#### **Surface SVI**

Consider now the following extension of the natural SVI parameterization:

#### Surface SVI (SSVI) parameterization

(3) 
$$w(k, \theta_t) = \frac{\theta_t}{2} \Big\{ 1 + \rho \varphi(\theta_t) k + \sqrt{(\varphi(\theta_t)k + \rho)^2 + (1 - \rho^2)} \Big\}$$

with  $\theta_t > 0$  for t > 0, and where  $\varphi$  is a smooth function from  $(0, \infty)$  to  $(0, \infty)$  such that the limit  $\lim_{t \to 0} \theta_t \varphi(\theta_t)$  exists in  $\mathbb{R}$ .

# Interpretation of SSVI

- This representation amounts to considering the volatility surface in terms of ATM variance time, instead of standard calendar time.
- The ATM total variance is  $heta_t = \sigma_{
  m BS}^2(0,t)\,t$  and the ATM volatility skew is given by

$$\left. \partial_k \sigma_{ ext{BS}}(k,t) 
ight|_{k=0} = rac{1}{2\sqrt{ heta_t t}} \partial_k w(k, heta_t) 
ight|_{k=0} = rac{
ho\sqrt{ heta_t}}{2\sqrt{t}} arphi( heta_t).$$

• The smile is symmetric around at-the-money if and only if ho=0, a well-known property of stochastic volatility models.

# Conditions on SSVI for no calendar spread arbitrage

#### Theorem 4.1

The SSVI surface [(3)](#eq3:ssvi) is free of calendar spread arbitrage if and only if

- 1.  $\partial_t \theta_t \geq 0$ , for all  $t \geq 0$ ;
- 2.  $0 \le \partial_{\theta}(\theta\varphi(\theta)) \le \frac{1}{\rho^2} \left(1 + \sqrt{1 \rho^2}\right) \varphi(\theta)$ , for all  $\theta > 0$ , where the upper bound is infinite when  $\rho = 0$ .

- In particular, SSVI is free of calendar spread arbitrage if:
  - the skew in total variance terms is monotonically increasing in trading time and
  - the skew in implied variance terms is monotonically decreasing in trading time.
- In practice, any reasonable skew term structure that a trader defines will have these properties.

# Conditions on SSVI for no butterfly arbitrage

#### Theorem 4.2

The volatility surface [(3)](#eq3:ssvi) is free of butterfly arbitrage if the following conditions are satisfied for all  $\theta > 0$ :

- 1.  $heta arphi( heta) \left(1+|
  ho|
  ight) < 4;$
- 2.  $heta arphi( heta)^2 (1+|
  ho|) \leq 4$ .

#### Remark

Condition  $\underline{1}$  needs to be a strict inequality so that  $\lim_{k\to +\infty} d_+(k) = -\infty$  and the SVI density integrates to one.

# Are these conditions necessary?

#### Lemma 4.2

The volatility surface [(3)](#eq3:ssvi) is free of butterfly arbitrage only if

$$\theta \varphi(\theta) (1 + |\rho|) \le 4$$
, for all  $\theta > 0$ .

Moreover, if  $heta \varphi(\theta)$  (1+|
ho|)=4, the surface [(3)](#eq3:ssvi) is free of butterfly arbitrage only if

$$\theta \varphi(\theta)^2 (1+|\rho|) \le 4.$$

So the theorem is almost if-and-only-if.

# The Roger Lee arbitrage bounds

• The asymptotic behavior of the surface (3) as |k| tends to infinity is

$$w(k, heta_t) = rac{(1\pm
ho)\, heta_t}{2}arphi( heta_t)\,|k| + \mathcal{O}(1), \quad ext{for any } t>0.$$

- Thus the condition  $\theta\varphi(\theta)$   $(1+|\rho|)\leq 4$  of Theorem 4.2 corresponds to the upper bound of 2 on the asymptotic slope established by Roger Lee.
  - Again, Condition 1 of the theorem is necessary.

## No static arbitrage with SSVI

#### Corollary 4.1

The SSVI surface [(3)](#eq3:ssvi) is free of static arbitrage if the following conditions are satisfied:

1. 
$$\partial_t \theta_t \geq 0$$
, for all  $t > 0$ 

2. 
$$0 \leq \partial_{ heta}( heta arphi( heta)) \leq rac{1}{
ho^2}ig(1+\sqrt{1-
ho^2}ig)\,arphi( heta)$$
, for all  $heta>0$ ;

3. 
$$\theta \varphi(\theta) \left(1+|\rho|\right) < 4$$
, for all  $\theta > 0$ ;

4. 
$$\theta \varphi(\theta)^2 (1+|\rho|) < 4$$
, for all  $\theta > 0$ .

A large class of simple closed-form arbitrage-free volatility surfaces!

#### A Heston-like surface

#### Example 4.1

The function  $\varphi$  defined as

$$arphi( heta) = rac{1}{\lambda heta} iggl\{ 1 - rac{1 - \mathrm{e}^{-\lambda heta}}{\lambda heta} iggr\} \,,$$

with  $\lambda \geq (1+|
ho|)/4$  satisfies the conditions of [Corollary 4.1](#cor:NoStaticArb).

This function is consistent with the implied variance skew in the Heston model as shown
in [The Volatility Surface]<sup>[3]</sup> (equation 3.19).

# A power-law surface

#### Example 4.2

The choice

$$arphi( heta) = rac{\eta}{ heta^{\gamma}\,(1+ heta)^{1-\gamma}}$$

gives a surface that is completely free of static arbitrage provided that  $\gamma\in(0,1/2]$  and  $\eta\left(1+|
ho|\right)\leq2.$ 

 This function is more consistent with the empirically-observed term structure of the volatility skew.

# Even more flexibility...

#### Theorem 4.3

Let  $(k,t)\mapsto w(k,t)$  be a SSVI volatility surface [(3)](#eq3:ssvi) satisfying the conditions of [Corollary 4.1](#cor:NoStaticArb) (in particular free of static arbitrage), and  $\alpha:\mathbb{R}_+\to\mathbb{R}_+$  a non-negative and increasing function of time. Then the volatility surface  $(k,t)\mapsto w_{\alpha}(k,\theta_t):=w(k,\theta_t)+\alpha_t$  is also free of static arbitrage.

- <u>Corollary 4.1</u> gives us the freedom to match three features of one smile (level, skew, and curvature say) but only two features of all the other smiles (level and skew say), subject of course to the given smiles being themselves arbitrage-free.
- Theorem 4.3 may allow us to match an additional feature of each smile through  $\alpha_t$ .

## How to eliminate butterfly arbitrage

- We have shown how to define a volatility smile that is free of butterfly arbitrage.
- This smile is completely defined given three observables.
  - The ATM volatility and ATM skew are obvious choices for two of them.
  - The most obvious choice for the third observable in equity markets would be the asymptotic slope for *k* negative and in FX markets and interest rate markets, perhaps the ATM curvature of the smile might be more appropriate.

#### How to fix butterfly arbitrage

• Supposing we choose to fix the SVI-JW parameters  $v_t$ ,  $\psi_t$  and  $p_t$  of a given SVI smile, we may guarantee a smile with no butterfly arbitrage by choosing the remaining parameters  $c_t'$  and  $\tilde{v}_t'$  according to SSVI as

$$c_t' = p_t + 2\,\psi_t, \quad ext{and} \quad ilde{v}_t' = v_t\,rac{4p_t c_t'}{\left(p_t + c_t'
ight)^2}.$$

• That is, given a smile defined in terms of its SVI-JW parameters, we are guaranteed to be able to eliminate butterfly arbitrage by changing the call wing  $c_t$  and the minimum variance  $\tilde{v}_t$ , both parameters that are hard to calibrate with available quotes in equity options markets.

## **Example: Fixing the Vogt smile**

• The SVI-JW parameters corresponding to the Vogt smile are:

$$(v_t, \psi_t, p_t, c_t, \tilde{v}_t)$$
  
=  $(0.01742625, -0.1752111, 0.6997381, 1.316798, 0.0116249)$ .

- We know then that choosing  $(c_t, \tilde{v}_t) = (0.3493158, 0.01548182)$  must give a smile free of butterfly arbitrage.
- There must exist some pair of parameters  $\{c_t, \tilde{v}_t\}$  with  $c_t \in (0.349, 1.317)$  and  $\tilde{v}_t \in (0.0116, 0.0155)$  such that the new smile is free of butterfly arbitrage and is as close as possible to the original one in some sense.

The R-code follows:

```
In [20]: t <- 1
    w <- a+b*(-rho*m + sqrt(m^2+sig^2))
    v <- w/t
    psi <- 1/sqrt(w)*b/2*(-m/sqrt(m^2+sig^2)+rho)
    p <- 1/sqrt(w)*b*(1-rho)
    c <- 1/sqrt(w)*b*(1+rho)
    wtilde <- (a+b*sig*sqrt(1-rho^2))
    vtilde <- wtilde/t

cprime <- vogtJW$pt + 2*vogtJW$psit
    vtildeprime <- vogtJW$vt*4*vogtJW$pt*cprime/(vogtJW$pt+cprime)^2;</pre>
```

```
In [21]: vogtFixedJW <- vogtJW
    vogtFixedJW$ct <- cprime
    vogtFixedJW$varmint <- vtildeprime

print(as.data.frame(rbind(vogtJW,vogtFixedJW)))

# Convert SVI-JW parameters back to raw SVI parameters
    vogtFixedParams <- jwToSvi(vogtFixedJW)
    print(vogtFixedParams)</pre>
```

### **Numerical optimization**

 In this particular case, choosing the objective function as the sum of squared option price differences plus a large penalty for butterfly arbitrage, we arrive at the following "optimal" choices of the call wing and minimum variance parameters that still ensure no butterfly arbitrage:

$$(c_t, \tilde{v}_t) = (0.8564763, 0.0116249).$$

- Note that the optimizer has left  $\tilde{v}_t$  unchanged but has decreased the call wing.
- The resulting smiles and plots of the function g are shown in <u>Figure 8</u>.

```
In [23]:
          # Now find values of ct and varmint that minimize distance from the orig
          inal curve
          strikes <-(-10:10)/10;
          callVals <- function(sviparams,k){</pre>
            BSFormula(1, exp(k), 1, 0, sigma=sqrt(svi(sviparams,k)))
          }
          callValsVogt <- callVals(vogtParams, strikes);</pre>
          obj <- function(par){</pre>
            c <- par[1]
            varmin <- par[2]</pre>
            vogtNewJW <- vogtJW</pre>
            vogtNewJW$ct <- c</pre>
            vogtNewJW$varmint <- varmin</pre>
            vogtNew <- jwToSvi(vogtNewJW)</pre>
            callValsNew <- callVals(vogtNew, strikes)</pre>
            # We need to also heavily penalize negative a
            arbVal<- sviSliceArbitrageCompute(vogtNew)$gArb</pre>
            return(sum((callValsNew-callValsVogt)^2)+100*arbVal^2)
          }
In [24]: | obj(par=c(vogtJW$ct,vogtJW$varmint))
Out[24]: [1] 0.2784265
In [25]: upperC=max(vogtJW$ct,vogtFixedJW$ct)
          lowerC=min(vogtJW$ct,vogtFixedJW$ct)
          upperV=max(vogtJW$varmint,vogtFixedJW$varmint)
          lowerV=min(vogtJW$varmint,vogtFixedJW$varmint)
          res <- optim(par=c(vogtJW$ct,vogtJW$varmint),</pre>
                        fn=obj,
                        method="L-BFGS-B",
                        lower=c(lowerC,lowerV),
                        upper=c(upperC,upperV))
          vogtOptimalJW <- vogtJW</pre>
          (vogtOptimalJW$ct <- res$par[1])</pre>
```

Out[25]: [1] 0.8564762 Out[25]: [1] 0.0116249

(vogtOptimalJW\$varmint <- res\$par[2])</pre>

## The Vogt smile fixed

Now we have found the "optimal" choices  $(c_t, \tilde{v}_t) = (0.8564763, 0.0116249)$ , let's plot the resulting smile:

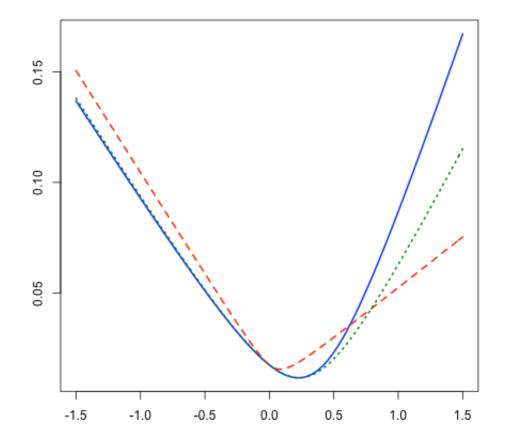

Figure 7: Plots of the total variance smile. The graph corresponding to the original Axel Vogt parameters is solid, to the guaranteed butterfly-arbitrage-free parameters dashed, and to the "optimal" choice of parameters dotted.

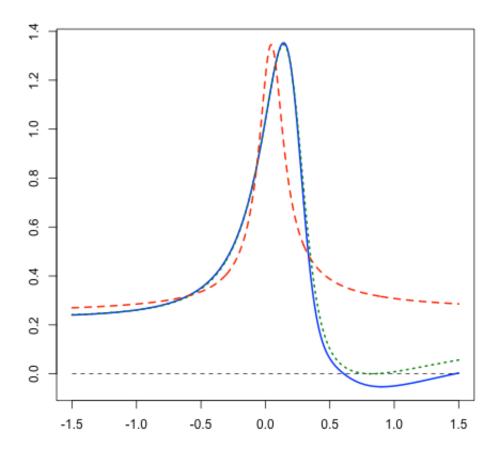

Figure 8: Plots of the function g. The graph corresponding to the original Axel Vogt parameters is solid, to the guaranteed butterfly-arbitrage-free parameters dashed, and to the "optimal" choice of parameters dotted.

## Why extra flexibility may not help

- The additional flexibility potentially afforded to us through the parameter  $\alpha_t$  of Theorem 4.3 sadly does not help us with the Vogt smile.
- For  $\alpha_t$  to help, we must have  $\alpha_t>0$ ; it is straightforward to verify that this translates to the condition  $v_t$   $(1-\rho^2)<\tilde{v}_t$  which is violated in the Vogt case.

```
In [33]: print(c(vogtJW$vt*(1-vogtParams$rho^2), vogtJW$varmint))
        [1] 0.01579453 0.01162490
```

### Generating implied vols

- We source raw index option price data from OptionMetrics In this case, the data file is spxOptionMetrics.rData.
- We use the function generateOptionMetricsIvols from optionMetricsToIVols.R to generate spxIvols050915.
- We use the function plotIvols from plotIvols.R to plot the results.

```
spxIvols050915 <- generateOptionMetricsIvols(spxData050915)
plotIvols(spxIvols050915)</pre>
```

#### Raw data

Raw OptionMetrics price data looks like this:

```
In [34]:
         load("spxOptionMetrics.rData")
         head(spxData050915)
Out[34]:
                            date symbol symbol_flag
                                                        exdate last_date cp_flag

```

Note that the strike prices are olut by a factor of 1,000! So let's fix them:

```
In [35]: spxData050915$strike_price <- spxData050915$strike_price/1000</pre>
```

### Implied volatility computation for index options

- We compute all implied volatilities from option price data
  - We don't need external estimates of interest rates and dividends
- We use put-call parity to get implied forward prices and discount factors.
  - Find the unique forward price and discount factor that minimize implied forward pricing errors.
- In this way, we can avoid errors due to non-synchronous parameter estimates and typically generate very smooth implied volatility curves.

#### **Detail of forward and PV estimation**

We choose the forward and the PV factor for each expiration so as to minimize the squared error in the put-call parity relationship:

# Implied volatility output

The resulting implied volatility output looks like this:

Out[37]:	id	Expiry	Техр	Strike	Bid	Ask	Fwd	CallM
		20050917	0.005475702	1150	NA	0.37535440	1227.798

# Implied volatility smiles: September 15, 2005

Finally plot the smiles:

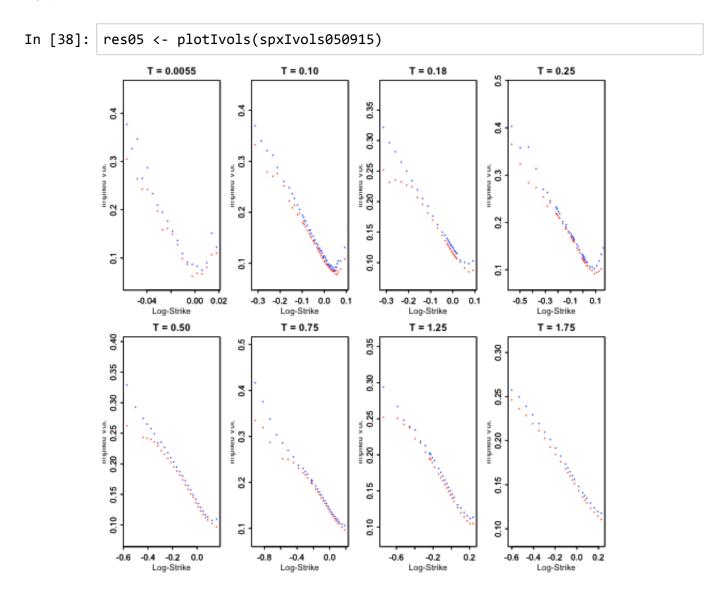

Figure 9: Here are the SPX implied volatility smiles corresponding to the output

## Single-stock options

- That's fine for index options which are European-style. What about single-stock options which are American-style?
- We can't use the same put-call parity trick we used before to impute forwards and PV factors.
- In principle, we have to take the whole volatility surface into account when pricing American options.
- Ignoring this however, given some American option model that takes discrete dividends as an input, we can impute interest rates and borrow costs for single-stocks.
  - We choose these to minimize the difference between call and put implied volatilities.

## SVI parameters used in The Volatility Surface

Here are the SVI parameters corresponding to the SVI fit shown in Figures 3.2 and 3.3 of *The Volatility Surface*:

```
In [41]: | texp <- sort(unique(spxIvols050915$Texp))</pre>
          svidata <- c(
          c(-0.0001449630, 0.0092965440, 0.0196713280, -0.2941176470, -0.005427323)
           c(-0.000832134 , 0.024439766 , 0.069869455 , -0.299975308 , 0.02648364
          ),
          c(-0.0008676750, 0.0282906450, 0.0873835580, -0.2892204290, 0.059270300
          0),
          c(-0.0000591593, 0.0331790820, 0.0812872370, -0.3014043240, 0.065254921
           c(0.0011431940 , 0.0462796440, 0.1040682980, -0.3530782140, 0.094200077
          0),
           c(0.0022640980 , 0.0562604150, 0.1305339330, -0.4387409470, 0.111123069
          0),
           c(0.0040335530, 0.0733707550, 0.1707947600, -0.4968970370, 0.149660916
          c(0.0034526910 , 0.0917230540, 0.2236814130, -0.4942213210, 0.185412849
          0));
          sviMatrix <- as.data.frame(t(array(svidata,dim=c(5,8))));</pre>
          colnames(sviMatrix)<-c("a","b","sig","rho","m")</pre>
```

```
In [40]:
         # Inspect the matrix
         sviMatrix
Out[40]:
                                            sig
         1 -0.0001449630 0.009296544 0.01967133 -0.2941176 -0.005427323

                                                            0.094200077
           0.0022640980 0.056260415 0.13053393 -0.4387409
                                                            0.111123069
            0.0040335530 0.073370755 0.17079476 -0.4968970
                                                            0.149660916
            0.0034526910 0.091723054 0.22368141 -0.4942213
                                                            0.185412849
```

### **Equivalent SVI-JW parameters.**

We note that for longer expirations, JW parameters are almost independent of expiration:

```
In [42]:
         sviToJw(sviMatrix,texp)
Out[42]:
                               psit
                                           pt
                                                     ct
                                                            varmint
                                                                            texp
         1 0.005461444 -0.02393127 2.1999949 1.1999972 0.005446544 0.005475702

```

## SVI fit example: September 15, 2005

Now check the quality of the SVI fit:

In [43]: res05 <- plotIvols(spxIvols050915,sviMatrix);</pre>

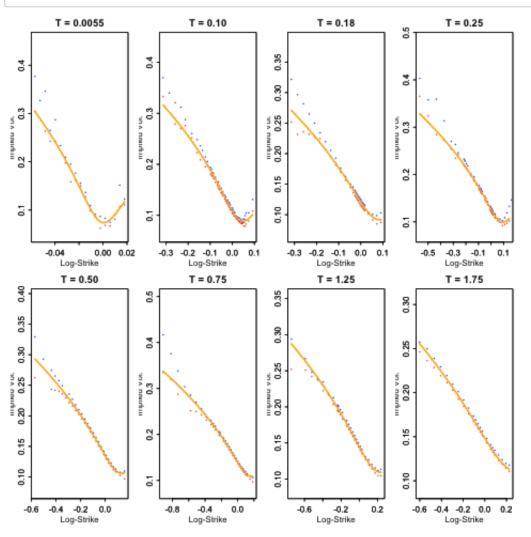

Figure 10: This fit is the one shown in Figure 3.3 of The Volatility Surface

#### Comments on the SVI fit

- It's hard to deny that this SVI fit is strikingly good.
  - At least in this particular case, the SVI parameterization gives an arbitrage-free surface with very good fits to the data.
- We would like to achieve a similar fit quality using only simple code written in R.

## SPX total variance plot as of 15-Sep-2005

In [44]: plotSVI(sviMatrix)

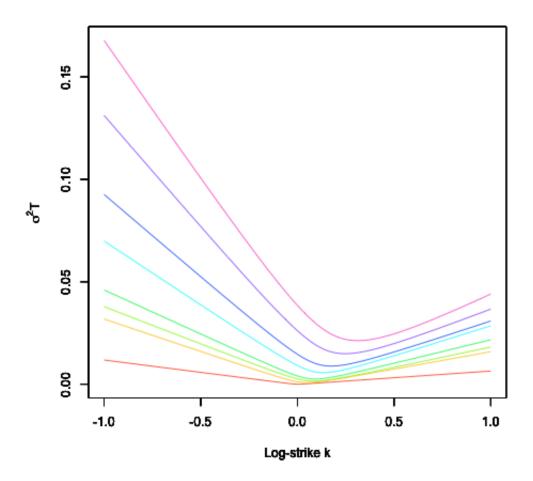

Figure 11: SVI fits to the SPX implied volatility surface as of the close on September 15, 2005, the day before triple witching.

# SPX total variance plot as of 15-Sep-2005: zoomed version

```
In [45]: plotSVI(sviMatrix,xrange=c(-.25,.25),yrange=c(0,0.01))

# Add a circle around the area of interest
y19 <- svi(sviMatrix[2,],.19)
points(x=.18,y=y19,pch=1,cex=10,pty=2,col="dark green")</pre>
```

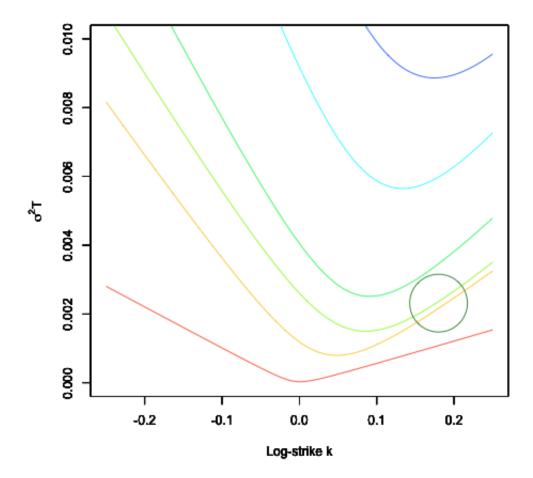

Figure 12: A zoomed view of the same plot showing lines getting very close to each other: small local variances!

## The total variance plot: observations

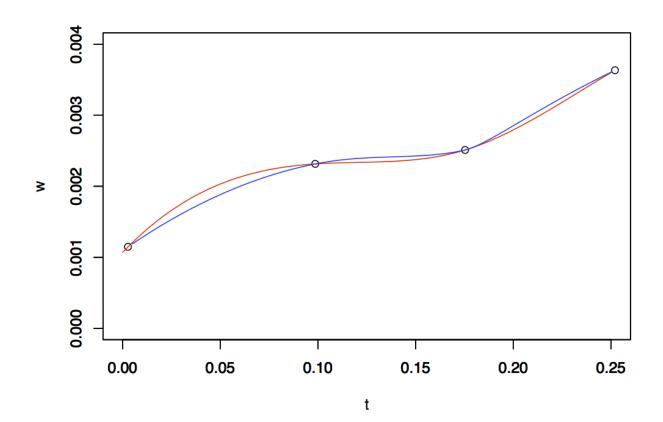

- Note that none of the lines cross: w is a non-decreasing function of t for every log-strike k
- No calendar spread arbitrage is equivalent to no lines crossing.
  - Negative calendar spreads (lines crossing) are equivalent to negative local variances
  - Recall that (equation (1.6) on page 11):

$$v_{loc}(k,T) = rac{\partial_T C}{rac{1}{2} \, K^2 \, \partial_{K,K} C}$$

- Lines moving together mean low local variance
- Lines moving apart mean high local variance

## Stineman interpolation

- Monotonic spline interpolation is essential. Stineman spline is a particularly attractive choice.
- Here's the term structure of total variance at constant k=0.19 (red is cubic spline, blue is Stineman spline):

• We see that the cubic spline generates local variances that are too small – they can even go negative.

## Fitting SVI slice-by-slice

Fitting slice-by-slice is not a good idea. Let's see why:

```
In [46]: spxOptData <- spxIvols050915

# Fit each slice individually
fit0 <- sviFit(spxOptData)
plotSVI(fit0,yrange=c(0,.1))</pre>
```

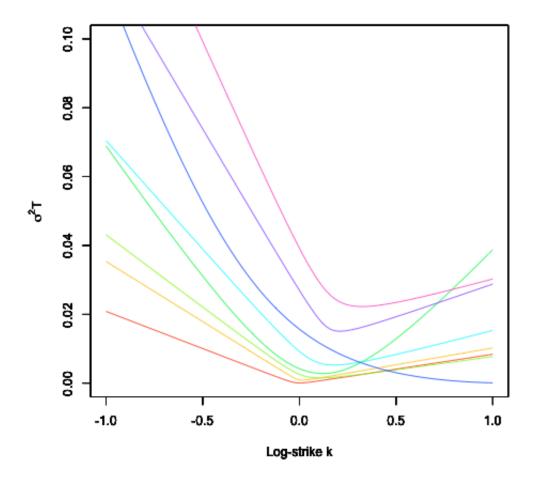

Figure 13: If we fit the slices independently, we see arbitrage everywhere!

In [47]: plotIvols(spxOptData,fit0)

#### Out[47]: \$expiries

[1] 0.005475702 0.101300479 0.177960301 0.254620123 0.503764545 0.75290 8966

[8] -0.2052787

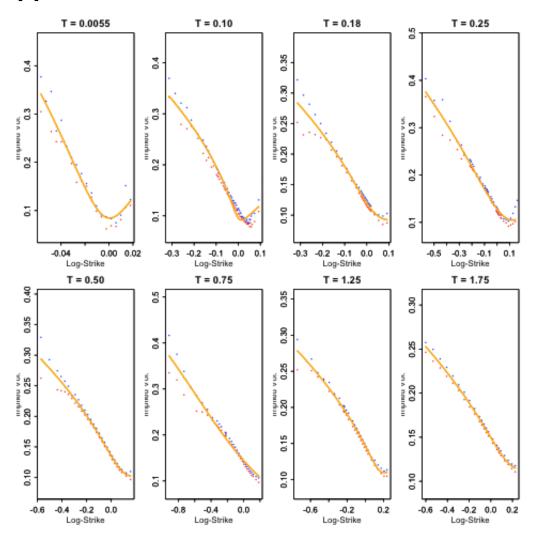

Figure 14: ...but fits to individual slices are good

## Fitting with no calendar spread arbitrage

- To achieve a fit with no calendar spread arbitrage:
  - We need to find explicit constraints on the parameters.
  - We need a good initial guess.

## The SVI square root parameterization

Consider the following special case of SSVI:

**SVI** square-root parameterization

$$w(k, heta_t) = rac{ heta_t}{2} \Big\{ 1 + 
ho arphi( heta_t) k + \sqrt{\left(arphi( heta_t) k + 
ho
ight)^2 + \left(1 - 
ho^2
ight)} \Big\}$$

with

$$arphi( heta) = rac{\eta}{\sqrt{ heta}}.$$

• The SVI square-root parameterization is free of static arbitrage for up to some (very long in practice) expiration.

Square-root fit example: September 15, 2005

In [48]: texp <- unique(spxOptData\$Texp)
 fitSqrt <- sviSqrtFit(spxOptData)
 plotIvols(spxOptData,fitSqrt)</pre>

#### Out[48]: \$expiries

[1] 0.005475702 0.101300479 0.177960301 0.254620123 0.503764545 0.75290 8966

[8] -0.2052787

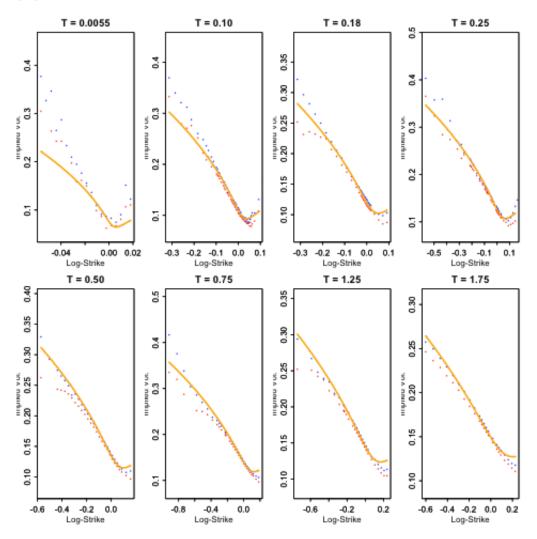

Figure 15: SVI square-root fits surprisingly well! ... except for the front month.

And here's the total variance plot:

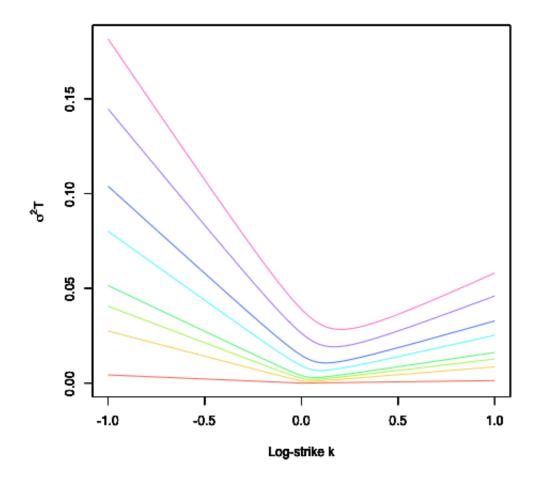

Figure 16: ... and there is no calendar spread arbitrage

#### **Quote-driven vs order-driven markets**

- In quote-driven markets, we have tight bid-offer prices for all listed options. Our fit must necessarily go through all of the bids and offers.
- In order-driven markets, it's not so clear what the current market price of an option is:
  - We may have a bid with no ask
  - Or an ask with no bid.
  - Or neither a bid nor an ask.
  - Or the bid-ask spread may just be very wide.
- In order-driven options markets therefore, the square-root fit may be more than adequate –
   even preferable because it has so few parameters and is therefore very robust.
- In quote-driven markets, we need to do better than the square-root fit.

## Quantifying lines crossing

- Consider two SVI slices with parameters  $\chi_1$  and  $\chi_2$  where  $t_2 > t_1$ .
- We first compute the points  $k_i$   $(i=1,\ldots,n)$  with  $n\leq 4$  at which the slices cross, sorting them in increasing order. If n>0, we define the points  $\tilde{k}_i$  as

$$egin{array}{ll} ilde{k}_1 &:= k_1 - 1, \ ilde{k}_i &:= rac{1}{2} \, (k_{i-1} + k_i), & ext{if } 2 \leq i \leq n, \ ilde{k}_{n+1} &:= k_n + 1. \end{array}$$

• For each of the n+1 points  $ilde{k}_i$ , we compute the amounts  $c_i$  by which the slices cross:

$$c_i = \max\left[0, w( ilde{k}_i, \chi_1) - w( ilde{k}_i, \chi_2)
ight].$$

#### Crossedness

#### **Definition 4.4**

The \*crossedness\* of two SVI slices is defined as the maximum of the  $c_i$   $(i=1,\ldots,n)$ . If n=0, the crossedness is null.

# **Computing crossedness**

To see if lines cross and to compute crossedness, call ComputeSviRoots from sviRoots.R. For example if we have:

```
In [50]: # Make the Lines cross
    svi2 <- sviMatrix[1:2,]
    svi2$a[2] <- svi2$a[2]-0.0005
    plotSVI(svi2)</pre>
```

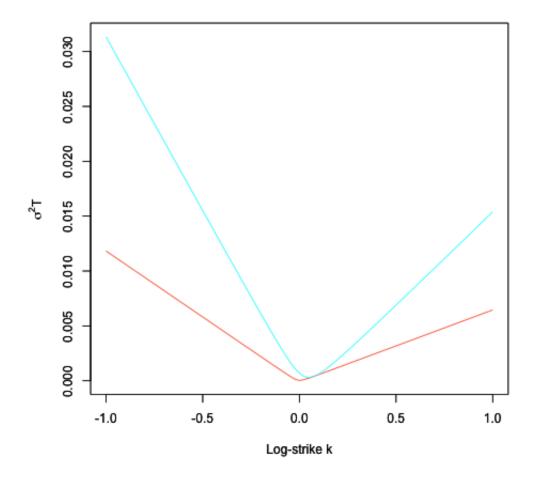

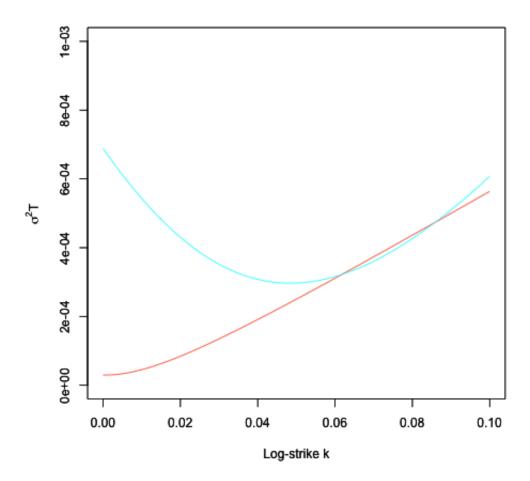

Figure 17: We lower slice 2 in order to introduce calendar spread arbitrage (crossed lines).

```
In [33]: # Zoom in to the problem area
plotSVI(svi2,xrange=c(0,0.1),yrange=c(0,0.001))
```

Calling sviRoots() on these two slices gives:

[1] 1.402099e-05

```
In [51]: sviRoots(svi2)
Out[51]: $roots
       [1] 0.06175203 0.08590506
       $crossedness
```

## **QR** fit

Finally, using *fitSqrt* as an initial guess, change SVI parameters slice-by slice, working backwards, so as to minimize the sum of squared distances between the fitted prices and the mid option prices with a big penalty for crossing either the previous slice or the next slice (as quantified by the crossedness).

In [52]: fitQR <- sviFitQR(spxOptData,fitSqrt)</pre>

In [53]: res <- plotIvols(spxOptData,fitQR)</pre>

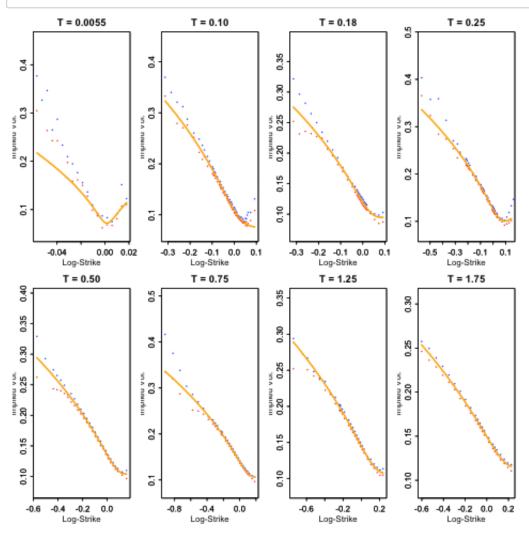

Figure 18: fitQR slice-by-slice fit quality

Let's check one of the slices:

In [54]: res <- plotIvols(spxOptData,fitQR,slices=4)</pre>

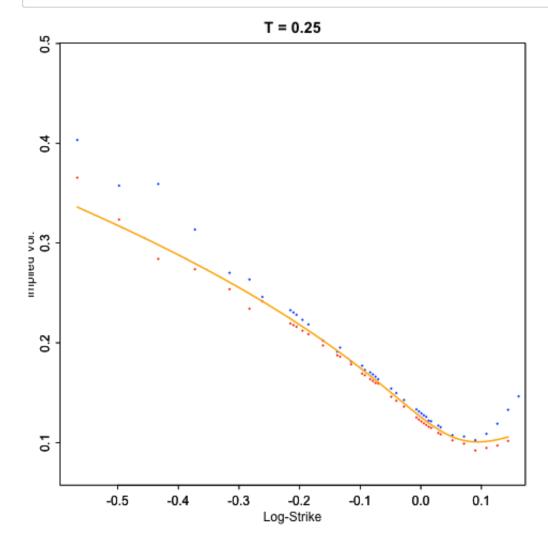

Figure 20: SPX Dec-2011 option quotes as of 3pm on 15-Sep-2011. Red triangles are bid implied volatilities; blue triangles are offered implied volatilities; the orange solid line is the QR SVI fit (*fitQR*).

And now for the total variance plot:

In [38]: plotSVI(fitQR)

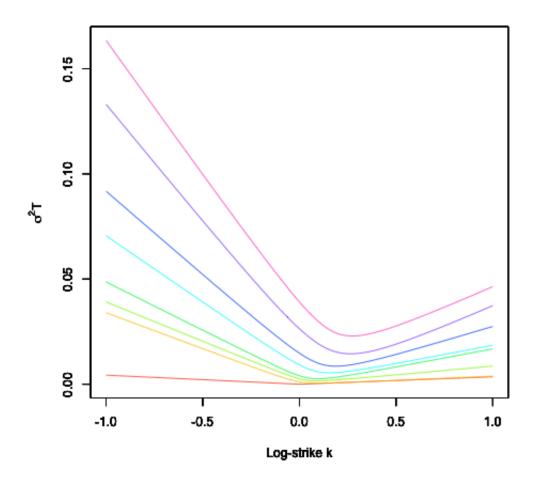

Figure 21: fitQR total variance plot: No calendar spread arbitrage!

However, it does look as if there are some very small local variances...

In [55]: plotSVI(fitQR,yrange=c(0,0.05))

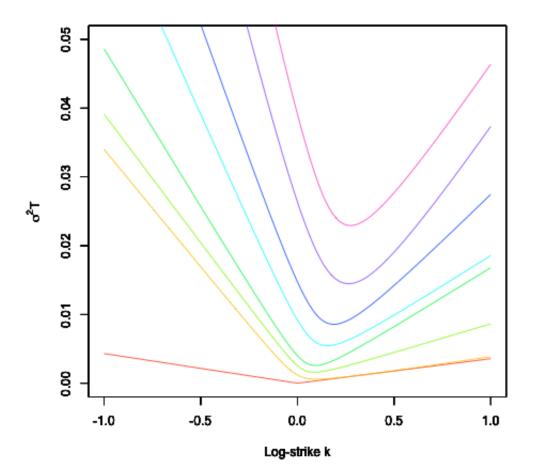

Figure 22: Closeup of the fitQR total variance plot: No calendar spread arbitrage, but very close...

Now we plot the empirical term structure of ATM volatility skew  $\left.\partial_k\sigma_{\mathrm{BS}}(k,T)\right|_{k=0}$ 

In [40]: plot(texp,res05\$atmSkew,col="red",pch=20)

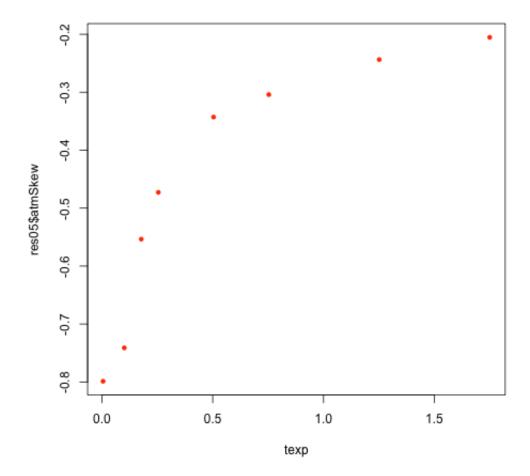

Figure 23: Empirical term structure of ATM volatility skew  $\partial_k \sigma_{\mathrm{BS}}(k,T)|_{k=0}$ 

Now we check the various fitted surfaces for calendar spread arbitrage:

In [56]: print(sviCalendarArbitrageCheck(sviMatrix)) # The pre-cooked fit
 print(sviCalendarArbitrageCheck(fit0)) # The fit slice-by-slice
 print(sviCalendarArbitrageCheck(fitSqrt)) # The sqrt fit
 print(sviCalendarArbitrageCheck(fitQR)) # The final optimized fit

[1] 0 [1] 0.1272942 [1] 0

[1] 0

and then for butterfly arbitrage:

```
In [57]: print(sviSliceArbitrageCheck(sviMatrix))
    print(sviSliceArbitrageCheck(fit0))
    print(sviSliceArbitrageCheck(fitSqrt))
    print(sviSliceArbitrageCheck(fitQR))

numeric(0)
    [1] 1
    numeric(0)
    numeric(0)
```

## Summary of the calibration recipe

- Given mid implied volatilities  $\sigma_{ij}=\sigma_{\rm BS}(k_i,t_j)$ , compute mid option prices using the Black-Scholes formula.
- Fit the square-root SVI surface by minimizing sum of squared distances between the fitted prices and the mid option prices. This is now the initial guess.
- Starting with the square-root SVI initial guess, change SVI parameters slice-by slice so as to
  minimize the sum of squared distances between the fitted prices and the mid option prices
  with a big penalty for crossing either the previous slice or the next slice (as quantified by the
  crossedness from <u>Definition 4.4</u>).

Finally, let's compare the pre-cooked surface with *fitQR*:

```
In [58]: volTVS <- function(k,t){sqrt(sviW(sviMatrix,texp,k,t)/t)}</pre>
          # 3D plot of TVS volatility surface
              k \leftarrow seq(-.5,.5,0.01) # Vector of log-strikes
              t <- seq(0.04,1.74,0.02) # Vector of times
              z <- t(volTVS(k,t)); # Array of volatilities</pre>
              # Add colors
              nbcol <- 100;
              color <- rainbow(nbcol,start=.3,end=.5);</pre>
              nrz <- nrow(z)</pre>
              ncz <- ncol(z)</pre>
              # Compute the z-value at the facet centres
              zfacet \leftarrow z[-1, -1] + z[-1, -ncz] + z[-nrz, -1] + z[-nrz, -ncz]
              # Recode facet z-values into color indices
              facetcol <- cut(zfacet, nbcol);</pre>
              # Generate 3D plot
              persp(k, t, z, col=color[facetcol], phi=30, theta=30,
                   r=1/sqrt(3)*20,d=5,expand=.5,ltheta=-135,lphi=20,ticktype="simpl
          e",
                   shade=.8,border=NA,xlab="Log-strike k",ylab="Expiration t",zla
          b="Implied vol.");
```

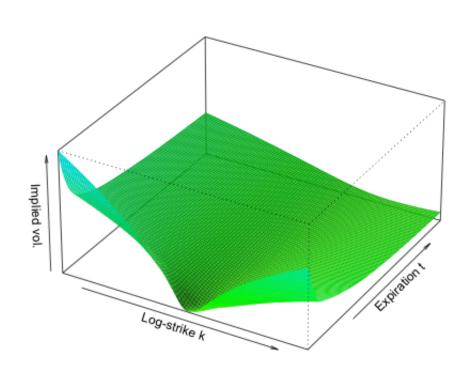

Figure 24: 3D plot of the pre-cooked SVI fit to the SPX implied volatilities as of September 15, 2005

```
In [59]: volTVS <- function(k,t){sqrt(sviW(fitQR,texp,k,t)/t)}</pre>
          # 3D plot of TVS volatility surface
              k \leftarrow seq(-.5,.5,0.01) # Vector of log-strikes
              t <- seq(0.04,1.74,0.02) # Vector of times
              z <- t(volTVS(k,t)); # Array of volatilities</pre>
              # Add colors
              nbcol <- 100;
              color <- rainbow(nbcol,start=.3,end=.5);</pre>
              nrz <- nrow(z)</pre>
              ncz <- ncol(z)</pre>
              # Compute the z-value at the facet centres
              zfacet \leftarrow z[-1, -1] + z[-1, -ncz] + z[-nrz, -1] + z[-nrz, -ncz]
              # Recode facet z-values into color indices
              facetcol <- cut(zfacet, nbcol);</pre>
              # Generate 3D plot
              persp(k, t, z, col=color[facetcol], phi=30, theta=30,
                   r=1/sqrt(3)*20,d=5,expand=.5,ltheta=-135,lphi=20,ticktype="simpl
          e",
                   shade=.8,border=NA,xlab="Log-strike k",ylab="Expiration t",zla
          b="Implied vol.");
```

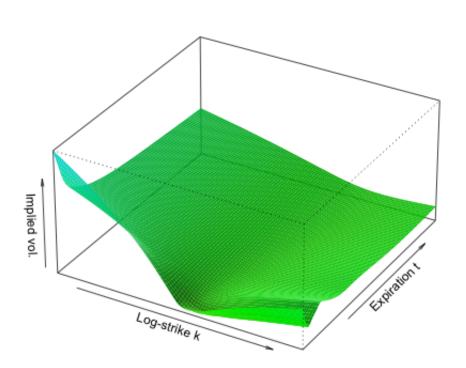

Figure 25: 3D plot of the QR fit to the SPX implied volatilities as of September 15, 2005

Note that the QR fit looks almost as good as the pre-cooked one.

## Choice of objective function

- A 0.1% volatility error on an ATM option is a much bigger pricing error than on a very far out-of-the-money option.
- Practitioners take this into consideration by vega-weighting their fits.
- · From the Black-Scholes formula:

$$ext{vega} = \sqrt{T}\,K\,rac{e^{-d_2^2/2}}{\sqrt{2\,\pi}} = \sqrt{T}\,F\,rac{e^{-d_1^2/2}}{\sqrt{2\,\pi}}$$

· Alternatively, weight by the reciprocal of the bid-ask volatility spread.

# Now we repeat the whole calibration recipe for 15-Sep-2011

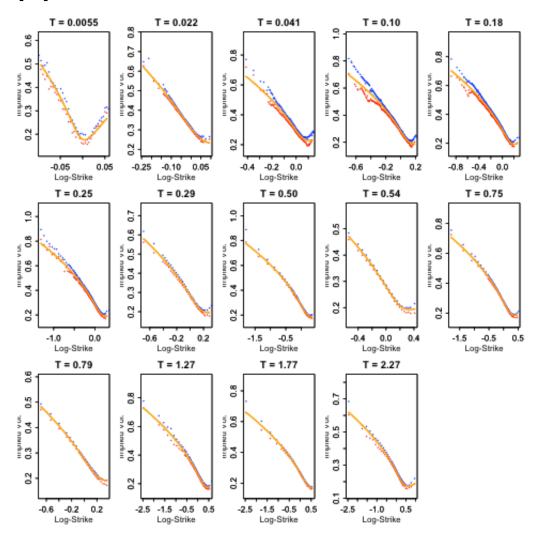

Figure 26: SPX option quotes as of 3pm on 15-Sep-2011. Red triangles are bid implied volatilities; blue triangles are offered implied volatilities; the orange solid line is the quartic roots (QR) SVI fit.

## SVI square-root calibration: December 2011 detail

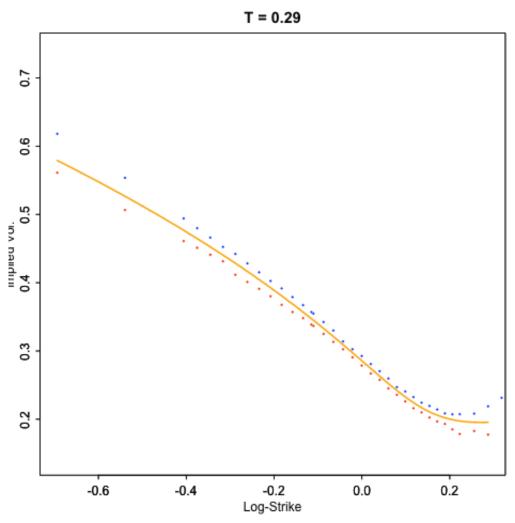

Figure 27: SPX Dec-2011 option quotes as of 3pm on 15-Sep-2011. Red triangles are bid implied volatilities; blue triangles are offered implied volatilities; the orange solid line is the quartic roots SVI fit

In [63]: # 15-Sep-2011 SPX smile to Mar-2011
foo <- plotIvols(spxIvols110915,fitQR110915,slices=8)</pre>

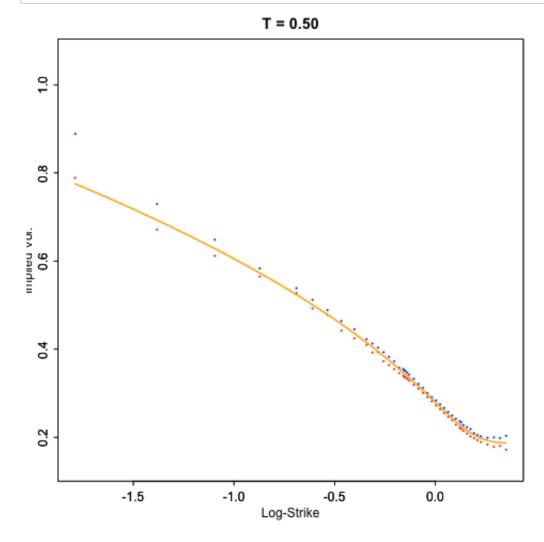

Figure 28: SPX Mar-2012 option quotes as of the close on 15-Sep-2011. Red triangles are bid implied volatilities; blue triangles are offered implied volatilities; the orange solid line is the SVI fit

# **Postscript**

You now have code to generate an SVI fit to market European option prices in OptionMetrics format or alternatively, implied volatilities in standard format.
